In recent years, an increasing number of drugs are administered through controlled-release formulations. This is true for a variety of different active ingredients, including, but not limited to, heparin, lovastatin and omeprazole. It is also true for a variety of different controlled-release drug delivery systems such as, for example, osmotic systems, multi-layer coated pellets and implants. One class of controlled-release formulations is made possible by using a delayed-release drug delivery system containing an active ingredient and one or more excipients which are insoluble or only sparingly soluble in the physiological environment of the organism. The active ingredient is intimately mixed with the excipient(s) and is prepared in a form from which the excipient(s) are gradually released upon ingestion, thereby providing the desired prolonged release of the active ingredient. In general, the excipients are selected so as to provide the desired combination of physical properties to the delivery system. The excipients are typically chosen from among low-cost inert materials, which can be readily processed and which produce a system that is relatively insensitive to variable environmental conditions such as, for example, water, when employed in vivo. In recent years, controlled-release drug delivery systems have been manufactured by a variety of techniques and from a variety of excipients. One such technique is a multi-layered tablet or capsule where the active ingredient is located in a central core and is encapsulated by one or more outer layers of different materials. The outer layers typically provide the desired controlled-
